**TRANSGENIC PLANTS AND****METHOD FOR NODE SEGMENT TRANSFORMATION**

5

**BACKGROUND OF THE INVENTION**

The invention relates generally to the genetic transformation of plants and, more particularly, to a method for producing a transgenic monocotyledonous plant by introducing foreign genetic material directly into a node segment of a non-transgenic plant and then regenerating and selecting for a transgenic plant. Publications referred to in this specification are alphabetically listed at the end of the description.

The agriculture industry has benefitted from recent advances in the field of biotechnology that have enabled the development of hardier varieties of plants for crop improvement and ornamental purposes. In particular, the use of sophisticated recombinant DNA techniques has resulted in the production of genetically improved monocotyledonous grass cultivars, including cereal crops, forage grasses and turfgrasses, and dicotyledonous cultivars, such as tobacco, having increased yields, herbicide resistance, disease resistance, pest resistance, stress tolerance, durability, and the like.

The importance of improved cereal crops (e.g. maize, wheat, rice, barley) and forage grasses, such as ryegrasses (*Lolium* spp.), orchardgrasses (*Dactylis* spp.) and fescues (*Festuca* spp.), is well recognized. Turfgrasses are important for providing attractive ground cover, such as for residential lawns, and for providing a support for many recreational sports, such as baseball, soccer and golf. The maintenance of golf courses, for example, requires intensive turfgrass management programs, including pesticide and herbicide treatments to prevent diseases and remove unwanted weed grasses. Therefore, production of turfgrasses that are herbicide-resistant and disease-resistant is beneficial to the turfgrass industry. The turfgrass seed market is second only to that of hybrid seed corn in being the largest seed market in the US.

-2-

Monocotyledons are generally recalcitrant to manipulation *in vitro* and to genetic transformation. Although transfer of foreign genes into plants by infection with *Agrobacterium tumefaciens* containing plasmid DNA is routine for many dicotyledons that readily form callus after wounding, the procedure is not routinely applicable in monocotyledons in which callus formation and transformation is more difficult. In addition to *Agrobacterium*, two other conventional methods of gene delivery, protoplast transformation and biolistic transformation, have been used to produce transgenic monocotyledonous and dicotyledonous plants.

Until the present invention, regenerable embryogenic tissue cultures have provided the major resource for the genetic transformation of monocotyledons. For example, mature seeds have been commonly used to initiate embryogenic callus cultures to establish suspension cell cultures of cereals, forage grasses and turfgrasses. However, genotypic variation in outbreeding species, such as common ryegrasses, has been problematic because each seed-derived embryo possesses a unique genotype and it has been shown that standard culture conditions to induce embryogenesis are not optimal for every genotype. Therefore, embryogenic and suspension cell cultures from various sources have had to be selectively established on a species to species and genotype to genotype basis. Immature embryos and inflorescences have been used for callus initiation with pearl millet (*Pennisetum americanum*), Guinea Grass (*Panicum maximum* Jacq.), Napier Grass (*Pennisetum purpureum* Schum.) and perennial ryegrass (*Lolium perenne*). Basal sections of leaves have been used for callus initiation of orchardgrass (*Dactylis glomerata* L.) and tall fescue (*Festuca arundinacea* Schreb.). Chopped mature embryos have been used directly to establish suspension cultures of tall fescue, perennial ryegrass and Italian ryegrass (*Lolium multiflorum*); and both immature caryopses and mature seeds have been used to obtain embryogenic suspension cultures of

-3-

Italian ryegrass and tall fescue (Lee, 1996). Regeneration of fertile plants has been obtained from isolated vegetative meristems of Italian ryegrass and perennial ryegrass (Pérez-Vicente *et al.*, 1993), from shoot apex explants from foxtail millet (*Setaria italica* L.), and from suspension culture-derived protoplasts of meadow fescue (*Festuca pratensis* Huds.). Switchgrass (*Panicum virgatum* L.) plants have been micropropagated from axillary buds in node segments in tissue culture, but there are no reports of transformation (Alexandrova *et al.*, 1993).

Stable transformed callus lines and transgenic plants from callus of perennial ryegrass have been established. Transformed callus lines of Italian ryegrass have also been reported but transgenic plants have not been regenerable from these callus lines. Kentucky bluegrass (*Poa pratensis* L.) plants can be regenerated from protoplasts, embryogenic suspension cultures and seed-derived callus cultures, but there are no reports of transformation. Until the present invention, there have also been no reports of transformation of St. Augustinegrass (*Stenotaphrum secundatum* [Walt] Kuntze), although plants have been regenerated from immature embryo-derived callus (Kuo *et al.*, 1993).

Protoplast transformation has been used to obtain transgenic turfgrasses, including orchardgrass, tall fescue, creeping bentgrass, redtop and red fescue. Direct DNA uptake by the protoplasts was enhanced by the use of polyethylene glycol (PEG) or electroporation. However, protoplast transformation has only been successful in a few cultivars of cereal crops and regeneration of cereal plants from protoplasts appears to be strongly genotype and culture condition dependent. Moreover, for regeneration of turfgrass protoplasts, nurse cells in the protoplast cultures are required. These have reportedly been provided by addition to the culture of agarose beads with adhered cultured nurse cells or by a nurse cell feeder layer (Lee, 1996).

-4-

Microprojectile (biolistic) bombardment has been used successfully to produce transgenic turfgrass, such as creeping bentgrass (Hartman, et al., 1994), perennial ryegrass, tall fescue and red fescue, from embryogenic callus and suspension cultures. Biolistic bombardment employs high velocity metal particles to deliver biologically active DNA into plant cells. The concept was first described by Klein et al. (1987) and has become a successful DNA delivery method in a number of plants. An advantage of biolistic transformation is that a variety of recipient cell types can be used, including embryogenic callus, suspension cell cultures, immature or even mature embryos. For those monocotyledonous species and cultivars that form embryogenic cultures, but a protoplast regeneration system is not easy to establish, biolistic genetic transfer is a possible alternative method for cell transformation.

Successful genetic transformation of dicotyledonous plants, particularly tobacco plants, have been reported. Transgenic callus cell lines of tobacco have been recovered after microprojectile bombardment of tobacco leaves (Tomes, et al.) and suspension cell cultures (Klein et al., 1988) and transgenic tobacco plants were regenerated after biolistic bombardment of tobacco leaves. There have also been reports of successful transformation of chloroplasts of tobacco using the biolistic process.

Transformation of dicotyledonous sunflower and soybean cells from a cotyledonary node associated with an apical meristem has been reported. However, successful transformation required tissue culture of the node cells in the presence of a cytokinin, prior to transformation, to induce the cells to differentiate into meristematic tissue cells and to become synchronized in the cell cycle (Tomes et al., 1991).

Transgenic perennial fruit plants (dicotyledons), such as cranberry, have been obtained from transformed stem tissue after biolistic bombardment. However, successful

-5-

transformation of the stem tissue required prolonged tissue culture in the presence of a cytokinin, prior to bombardment, to induce the formation of adventitious buds (Serres *et al.*, 1993).

5 Transformation efficiencies (the ratio of the number of cells transformed to the number of starting cells) are low, however, for each of the above-described transformation methods, being on the order of  $10^{-3}$  to  $10^{-6}$ .

10 In addition to the commonly used transformation techniques, available alternative methods for the direct introduction of foreign DNA into cells include silicon carbide fibers, electroporation of intact tissues, electrophoresis and microinjection. However, the stable expression of foreign genes, using these techniques, has  
15 yet to be established.

In view of the foregoing uncertainties and, in many cases, unreliability of current methods for successful transformation and regeneration of transgenic plants, there is a need for an efficient method of genetic transformation  
20 and regeneration that can be successfully applied to monocotyledonous plants, and particularly to turfgrasses, to obtain transgenic plants. Moreover, there is a need for a method of transforming monocotyledon plant cells that does not require extensive cell culture preparation and/or  
25 callus formation and/or extended tissue culture. Further, there is a need for improved techniques for genetic transformation and plant regeneration and selection systems for monocotyledons that allow introduction of foreign genetic material that alters the physical, biochemical  
30 and/or physiological properties of the plant to provide beneficial traits or reduce unwanted characteristics.

#### SUMMARY OF THE INVENTION

35 The invention provides a simple and efficient process for producing a transgenic monocotyledonous plant by inserting a foreign genetic material directly into a node segment of a stem of a plant and thereafter subjecting the node segment to culture conditions sufficient to permit

-6-

regeneration of the node segment into a plantlet. As used in the context of the invention, the term "node segment" includes any joint in a stem from where one or more leaves may grow and also includes any lateral (axillary) buds on the side of the stem, as in a leaf axil. The definition further includes node segments occurring in specialized stems known to those skilled in the art, such as rhizomes, stolons, tubers, bulbs, corms, cladophylls, and in stems modified with spines or tendrils. Preferably, the node segment is associated with an intercalary meristem. By direct transfer of the genetic material into node segment tissue, the process of the invention eliminates the extensive cell preparation, tissue dissection, and/or extended period in tissue culture required by previous transformation methods using embryonic cell or callus cultures, protoplasts or suspension cell cultures.

It has been discovered that *in vitro* regeneration of transgenic shoots from transformed node segment tissue does not require callus formation, at least in certain turfgrasses such as St. Augustinegrass. Therefore, the time period required for regeneration of transgenic plantlets from transformed node segment cells is greatly reduced in comparison to regeneration systems requiring callus formation.

The genetic material may be inserted into the node segment by any method of genetic transfer, such as those described above, but preferably is inserted by biolistic (microprojectile) bombardment, by transfer mediated by *Agrobacterium*, or by direct DNA uptake mediated by electroporation.

The process may be used to transform any plant that has a stem having at least one node segment. Therefore, the process may be used for monocotyledonous plants including, but not limited to cereal crops, forage grasses, turfgrasses, herbs, woody plants, vegetable plants and flowering plants. The process is particularly preferred for producing transgenic grasses, especially turfgrasses and other grasses that can be vegetatively

-7-

propagated, such as St. Augustinegrasses, bluegrasses, bentgrasses, bermudagrasses, buffalograsses, redtop, bahiagrasses, centipedegrass, zoysiagrasses, ryegrasses, fescues, and the like. Preferably, the node segments are associated with intercalary meristems.

By the process of the invention, transgenic plants may be produced that have one or more stable altered properties compared to a plant of the same species that is not transgenic for the property. Altered properties may be physical, biochemical or physiological in nature and include, but are not limited to, herbicide resistance, disease resistance, insect resistance, an improved nutritional content, expression of a pigment or a fragrance, and the like.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic illustration of a rye plant showing node, internode and intercalary meristem regions.

Figure 2 is a schematic illustration of an herbaceous monocotyledonous plant showing nodes, internodes and a rhizome.

Figure 3 is a schematic illustration of node segments having one, two or three vertical cuts in preparation for biolistic bombardment.

Figure 4 is a schematic illustration of three chimeric plasmids used for transforming St. Augustinegrass for herbicide resistance.

-8-

**DETAILED DESCRIPTION OF THE INVENTION**

In one embodiment, the invention concerns producing a transgenic plant from a genetically transformed node segment from a stem of a plant. Genetic transformation, according to the invention, is the stable integration of a foreign DNA into the genome of a plant cell, and includes integration of the foreign DNA into host cell nuclear DNA and/or extranuclear DNA in organelles (e.g. chloroplasts, mitochondria). The plant to be transformed may be a non-transgenic plant, or may be a plant that is already transgenic but comprises one or more foreign genes that are different than the new foreign gene or genes to be introduced. Foreign DNA is genetic material that is not indigenous to (not normally resident in) the plant before transformation or is not normally present in more than one copy. However, "foreign" DNA may include a further copy of an indigenous gene or genetic sequence that is introduced for purposes of co-suppression.

The foreign genetic material may comprise DNA from any origin including, but not limited to, plants, bacteria, viruses, bacteriophage, plasmids, plastids, mammals and synthetic DNA constructs. The DNA may be in circular or linear form and may be single-stranded or double-stranded. The DNA may be inserted into the host plant DNA in a sense or anti-sense configuration and in single-stranded or double-stranded form. All or part of the DNA inserted into the plant cell may be integrated into the genome of the host.

The node segment, according to the invention, may be obtained from a stem of any monocotyledonous plant that has at least one node. As described above, as used in the context of the invention, the term "node segment" includes any joint in a stem from where one or more leaves may grow and also includes any lateral (axillary) buds on the side of the stem, such as those occurring in a leaf axil. The part of the stem between two nodes is termed the "internode". Elongation of the stem occurs at the apex of the stem (apical meristem) and in the internode regions

-9-

(intercalary meristems). The term "node segment", as used in the context of the invention, preferably includes portions of internode regions which include intercalary meristems. The definition of "node segment" further  
5 includes node segments occurring in rhizomes, stolons, tubers, bulbs, corms, cladophylls, and in stems modified with spines or tendrils.

Examples of node segments suitable for use in the invention are illustrated Figure 1, adapted from a  
10 published figure (Esau, 1965). The illustrated plant 1 is a rye plant having five nodes 2a, 2b, 2c, 2d and 2e, five internodes 3a, 3b, 3c, 3d and 3e, and a spike 4. Leaf sheaths 5a, 5b, 5c, 5d and 5e extend upward from each node and terminate where leaf blades 6 diverge from them. The  
15 youngest tissue (intercalary meristems) 7 in the internodes 5b-5e is represented in black, somewhat older tissue 8 is hatched, and the most mature tissue 9 is white.

A node segment of the invention is a tissue excised from a plant stem, such as that illustrated in  
20 Figure 1, comprises at least one node and may include internode tissue from above and below the node. A suitable node segment, as illustrated in Figure 1, could contain one or more of nodes 2a-2e. The tissue above the node in the node segment may comprise the youngest tissue 7 and  
25 somewhat older tissue 8. Preferably the tissue above the node comprises the youngest intercalary meristem tissue 7. However, older intercalary meristem tissue may also be used because it is known that the meristematic activity in the region of the nodes can be reactivated even in mature  
30 stems. The tissue below the node in the node segment may comprise any or all of the tissue contained in the internode below the node of interest.

Figure 2 illustrates an herbaceous monocotyledon  
10 (an iris), suitable for use in the invention, consisting of roots 11, rhizome 12, stem 13, leaves 14 and flower 15.  
35 Nodes 16 and internodes 17 occur on the stem 13. The rhizome 12 is a specialized horizontal stem that grows below ground. The illustrated roots 11 are adventitious

-10-

roots growing from the rhizome (stem). The rhizome 12 has scalelike leaves and lateral buds at each node, with short to long internodes between the nodes.

The plant according to the invention includes any  
5 plant having a stem with at least one node, preferably associated with an intercalary meristem, and includes any plant so defined in the group *Monocotyledoneae* including, but not limited to, any plant falling within the major families and subfamilies, including *Bambusoideae* which  
10 includes bamboo, *Arundinoideae* which includes pampas grass and reeds, *Pooideae*, which includes oats, barley, rye, wheat, maize, corn, *Phalaenopsis*, *Poaceae* which includes the *Festucoideae*, namely *Chlorideae*, including millet, tef, Mitchell grass, Rhodes grass, bermudagrass, buffalograsses,  
15 Kallar grass and gramas, *Hordeae*, including wheatgrasses and ryegrasses, *Zoysieae*, including zoysiagrasses, *Agrostideae*, including bentgrasses, redtop, beachgrasses and timothys, *Festuceae*, including bromeagrasses, fescues and bluegrasses, and the *Panicoideae*, which includes St.  
20 Augustinegrasses, sorghum, maize, surinamgrass, pangolagrass, sugar cane, Vetivergrass, carpetgrasses, bahiagrasses and kikuyugrasses.

The plants suitable for use in the invention may be annual, biennial or perennial plants. Most preferably,  
25 the plant of the invention is any monocotyledonous plant that can be vegetatively propagated from a node segment to form a shoot and root system. For example, dumb cane (*Dieffenbachia maculata*) and asparagus (*Asparagus officinalis*) can be propagated from lateral buds and  
30 *Phalaenopsis* can be propagated from nodal sections.

In a preferred embodiment of the invention, the transforming DNA comprises one or more genes or partial genes that code for expression of an altered physical, biochemical or physiological property of the transgenic  
35 plant, compared with a plant of the same species that is not transgenic for the same property, to provide a beneficial trait or reduce an unwanted characteristic. Examples of characteristics that may be altered by genetic

-11-

transformation include, but are not limited to, herbicide resistance, disease resistance, insect resistance, drought resistance, dwarfism, improved nutrient utilization, antibiotic resistance, expression of a pigment, expression  
5 of a fragrance, improved nutritional content, increased production of seed, increased production of fruit, increased stress tolerance, expression of a regulatory gene to control indigenous genes, reduction of allergenic pollen production, and the like, and combinations of any of the  
10 foregoing.

The genetic techniques of the invention also contemplate modified plants having indigenous genetic sequences deleted or otherwise mutated.

Examples of genes that may be integrated into the  
15 host genome to produce a stable expression of an altered characteristic include, but are not limited to, the bar gene which confers the ability to detoxify bialaphos and the neomycin phosphotransferase II gene (NPTII) which confers resistance to the antibiotic kanamycin.

20 A process for producing a transgenic plant according to the invention comprises providing a node segment from a stem of a plant, inserting a foreign genetic material into the node segment, and subjecting the node segment to conditions sufficient to permit regeneration of  
25 the node segment into a new stably transformed plantlet.

Any method of introducing DNA into the cell of the node segment may be used in the invention including, but not limited to biolistic bombardment with DNA-coated microprojectiles, *Agrobacterium*-mediated delivery and  
30 direct DNA uptake mediated by electroporation, polyethylene glycol (PEG), silicon carbide fibers, electrophoresis or microinjection. The preferred techniques for delivering the DNA are biolistic bombardment, *Agrobacterium*, and direct uptake of DNA mediated by electroporation.

35 Although several methods for direct DNA delivery are known, preferably the DNA is delivered into the host cell by a transforming or cloning vector, such as plasmid. Selection and/or synthetic construction of plasmids

-12-

containing specific genes are well known in the art. Synthetic constructs of chimeric plasmids contain the gene or gene of interest and frequently comprise promoter and/or leader sequences obtained from diverse sources to facilitate insertion into the host genome. Examples of plasmids commonly used to transform plant cells include, but are not limited to, Ti plasmids (*Agrobacterium tumefaciens*) (Darnell, Lodish and Baltimore, 1990), a plasmid containing a  $\beta$ -glucuronidase gene (GUS) and/or a NPTII gene and a cauliflower mosaic virus (CaMV) promoter plus a leader sequence from alfalfa mosaic virus (Sanford *et al.*, 1993), a plasmid containing a *bar* gene cloned downstream from a CaMV 35S promoter and a tobacco mosaic virus (TMV) leader. Other plasmids may additionally contain introns, such as that derived from alcohol dehydrogenase (*adhI*), or other DNA sequences. The size of the vector is not a limiting factor. For example, intact bacterial cells (*e.g.* *Escherichia coli*) containing or transformed to contain a gene of interest can be delivered as biolistic projectiles.

The successful delivery of the DNA into a cell may be preliminarily evaluated by the transient expression of a "reporter" gene. A reporter gene is a component of the DNA used for transformation and may be the same as or different than the gene conferring another desired property. The property conferred on the transformed cell or tissue by the reporter gene is usually easily detectable. "Transient expression" denotes the expression, often cytoplasmic, of a gene before the gene has been stably integrated into the genome of the treated cells or tissue. For example, commonly used reporter genes are genes coding for the production of chloramphenicol acetyltransferase or neomycin phosphotransferase, which confer resistance to the antibiotics chloramphenicol and kanamycin, respectively, or the *E. coli*  $\beta$ -glucuronidase gene (*gusA*), the products of which can be detected by a histochemical assay. Genes conferring herbicide resistance can also be used as reporter genes. In this case, cells or

-13-

tissues may be tested for transient expression of the genes by culture in the presence of the herbicide. Shoots or plantlets growing in the presence of the herbicide are presumptively transformed. Confirmation of the integration of the gene into the genome of the host may be later confirmed by herbicide treatment of the resulting plants.

The node segment of the plant to be transformed is preferably cleared of any attached leaves prior to the transformation process. The tissue of the node segment is then trimmed to a desired size, preferably leaving a small amount of intercalary meristem tissue above the node. The foreign genetic material is preferably inserted into the node segment within about 48 hours of harvesting the node from the plant to minimize the possibility of shoot formation prior to transformation of the node segment. The node segment is placed in a Petri dish or other container containing a culture medium described further below prior to transformation.

An embodiment of the invention will now be described with respect to the transformation of turfgrasses, such as St. Augustinegrass, Kentucky bluegrass, creeping bentgrass, and the like, by biolistic transformation. However, as stated above, other transformation techniques may be employed and the invention methods may also be applied to other monocotyledonous plants. The method of the invention is particularly advantageous for transformation of turfgrasses and other monocotyledons that can be vegetatively propagated.

In one embodiment of the invention, illustrated in Figures 3A, 3B and 3C, if the node segment has a sufficient cross-sectional area, it may be useful to make a number of vertical cuts (dotted lines), preferably one to three, into the node segment 30, shown in Petri dish 32 containing culture medium 34, in order to increase the area exposed to the transformation vector. Alternatively, the node segments may remain uncut (not shown).

In another embodiment of the invention, callus formation may be induced in node segments having vertical

-14-

cuts by culturing the node segments on a callus induction medium based on that of Murashige and Skoog (MS medium) containing a biologically active hormone, 2,4-dichlorophenoxyacetic acid (2,4-D), in a range from about 1 to  
5 about 10 mg/L, preferably about 5 mg/L, L-asparagine (about 50 mg/L to about 75 mg/L) or an equivalent amino acid or chemical entity, preferably thiamine HCl (about 0.05 mg/L to about 5 mg/L) or equivalent. The medium may also  
10 contain MS medium minerals and/or potassium iodide or equivalent or functional analogue at 0.83 mg/L. Culture conditions of temperature and light for callus formation are known to those skilled in the art.

In a preferred embodiment, callus formation is not induced in the node segments prior to bombardment. The  
15 node segments are placed in MS medium that does not contain a callus inducing hormone, such as 2,4-D, and callus formation is prevented. The node segments are then bombarded directly. A particular advantage of this  
20 embodiment of the invention is elimination of the tissue culture callusing time, which can take from 1 to 10 weeks for some monocotyledons. Callus formation is not necessary for regeneration of node segments from, for example, St. Augustinegrass.

The addition of an osmoticum (i.e., a  
25 supplemental agent increasing osmolarity) to the culture/bombardment medium may dramatically increase the rate of transformation, although the optimum concentration for each plant species varies. Elevated osmoticum concentrations are thought to protect the cells from  
30 leakage or bursting and may also improve particle penetration. Suitable osmotica, such as mannitol, sorbitol and mixtures of these, are known by those skilled in the art. Osmoticum concentrations in MS medium containing asparagine (MSA medium), of zero to 0.1M mannitol/0.1M  
35 sorbitol to 0.3M mannitol/0.3M sorbitol are suitable for culture/bombardment of turfgrasses, such as St. Augustinegrass.

-15-

The microprojectiles for bombardment of the node segments are preferably tungsten or gold, although other particles are known in the art (Sanford *et al.*, 1993). Techniques for assessing the efficacy of the particle type are known in the art and are not herein described. Preferably, for turfgrasses, gold particles are employed, as these have been found to be less toxic to the cells than tungsten particles.

Techniques for coating the particles with DNA and bombarding plant and other cells are well known to those skilled in the art and are described in publications such as Sanford, 1993.

A further aspect of the invention includes a method for *in vitro* regeneration of a node segment of a plant to form a new transgenic plantlet, and comprises the steps of providing a node segment from a stem of a plant, introducing a foreign genetic material into a regenerable cell of the node segment, and culturing the node segment in a culture medium that does not contain callus-inducing hormones and, therefore, does not induce the formation of callus. Transfer of the node segment explants from the bombardment medium to regenerating culture medium may occur at any time after bombardment. For turfgrasses, transfer preferably occurs about 2-5 days after bombardment.

The regenerating culture medium may be the same or different than the culture/bombardment medium described above. The regenerating culture medium may contain shooting hormones and may additionally contain rooting hormones. A shooting hormone is a class of compounds known as cytokinins which includes synthetic shooting hormones, such as 6-benzyl-aminopurine (BAP), kinetin, zeatin, 2iP ( $N\beta(\Delta^2\text{-isopentenyl})\text{-adenine trans-6-(4-hydroxy-3-methylbut-2-enyl) amino purine}$ ). A rooting hormone is a class of compounds known as auxins which include indoleacetic acid, naphthaleneacetic acid and indolebutyric acid.

It has been found that certain turfgrass species, such as St. Augustinegrass, do not require a culture medium containing shooting and/or rooting hormones in order to

-16-

form shoots from node segments. Therefore, for regeneration of these turfgrasses, culture medium that does not contain these hormones is preferred. A preferred medium for regeneration of node segments of turfgrasses is  
5 MS basal medium without 2,4-D, 3% sucrose, and a chemical used for selection of transgenic plants (e.g. 1 mg/L bialaphos to select for transient expression of the gene conferring resistance to a herbicide, such as Herbiace™).

Healthy shoots from presumptive transgenic  
10 explants growing in the presence of the selection chemical are then rooted and transferred to a medium (in the absence of biologically active hormones), such as soil or potting mix.

The above conditions lead to regeneration of  
15 green plantlets and plants with photosynthetic ability. As described above, a test used for confirmation that the gene is stably integrated into the genome of the host plant necessarily depends on the property to be conferred to the plant. For example, when the property is herbicide  
20 resistance, confirmation may be achieved by treatment of the growing plants by spraying or painting the leaves with the herbicide in a concentration that is lethal for control plants that have not been subjected to the transformation process.

25 The invention also extends to transgenic plants produced by the methods of the invention and node segments, embryo cells, callus cells, protoplasts, leaves, meristems, fruit, vegetables and seeds from the transgenic plants.

The following examples of the process for node  
30 segment transformation and regeneration of monocotyledonous plants are presented to further illustrate various embodiments of the present invention. These examples are not to be considered limiting, however, as other monocotyledons, transforming genes, plasmids, methods of  
35 transformation, culture media, and the like, may be used in the practice of the invention.

-17-

**EXAMPLES****Biolistic Transformation of Node Segments and Regeneration of Transgenic St. Augustinegrass Plants**

St. Augustinegrass is a warm-season turfgrass used particularly for lawns in the southern United States. St. Augustinegrass is susceptible to a wide range of diseases, including dollar spot, brown patch, *Helminthosporium* spp., *Fusarium* blight, *Fusarium* patch, *Pythium* blight, red thread, stripe smut and *Typhula* blight. For these reasons, this grass species is an attractive target for biotechnology techniques. However, there have been no prior reports of transformation of St. Augustinegrass, or the regeneration of transgenic St. Augustinegrass plants.

**Establishment of the Selection Conditions**  
**Plasmids Used for Bombardment**

The constructs of the plasmids used for bombardment are illustrated in Figure 4.

**Examples 1-7**

In these examples, node segments of mature commercial cultivars of St. Augustinegrass were transformed using a synthetic chimeric *pat* (*bar*) gene. The stable integration and expression of the *pat* gene renders the plant resistant to the herbicide, phosphinothricin. The plasmid used for transformation was pSAN41 which contains the *pat* gene under the control of the rice actin 1 (*Act 1*) promoter and a nopaline synthase (*nos*) 3' terminator. The *Act 1* region is a ~1.3 kb fragment which contains the 5' flanking region, the site of transcription initiation, the first non-coding exon, the first intron and the start of the second exon of the rice gene.

**Examples 8-13**

In these examples, node segments of mature commercial cultivars of St. Augustinegrass were transformed using a chimeric *CP4* gene. The stable integration and

-18-

expression of the *CP4* gene renders the plant resistant to the herbicide glyphosate, the active ingredient in the herbicide Roundup™. The plasmids used for transformation were (i) pMON25488, which contains the *CP4* gene under the control of the 35S Cauliflower mosaic virus promoter with the rice actin intron and a *nos* 3' terminator, or (ii) plasmid pMON25496, which contains the 35S-*CP4-nos* 3' regions of pMON25488 and another *CP4* gene under the control of the rice actin 1 (*Act 1*) promoter.

#### Harvesting and Preparation of Node Segments for Biolistic Bombardment

Young nodes were excised from mature greenhouse grown St. Augustinegrass plants (Cultivar 6-89-196, The Scotts Company, Marysville, OH) and the leaves removed. Node segments (explants) of about 2 centimeters (cm) in length were sterilized with a solution of 10% Clorox and 0.075% (v/v) Tween-20 for 15 to 30 minutes, and then rinsed three times with sterile water. Tissues were trimmed from both ends of the explants, leaving less tissue above the node than below. One, two or three vertical cuts were made into the explants. Some explants did not receive cuts, but remained whole.

Plates were prepared for particle bombardment by placing approximately 10 nodal explants per Petri dish (cut end up, see Figure 3) in MSA2D media alone (Murashige and Skoog medium containing 130 mg/L asparagine and 2 mg/L 2,4-dichlorophenoxyacetic acid), MSA2D media containing 0.1M mannitol and 0.1M sorbitol, or MSA2D media containing 0.3M mannitol and 0.3 M sorbitol. Uncut explants were stood on end in the Petri dishes. Plates were prepared 20 hours prior to bombardment and kept in the light.

#### Preparation of Microprojectiles and DNA Samples and Biolistic Bombardment

In previous biolistic transformation experiments using creeping bentgrass, gold particles were found to be less toxic than tungsten particles. Therefore, gold

-19-

particles were selected as microprojectiles for biolistic transformation of the St. Augustinegrass node segments. Gold particles were prepared by soaking at room temperature in 100% ethanol for 15 minutes, centrifuged briefly, washed  
5 3 times in sterile, distilled water, and resuspended in water.

DNA samples consisting of 50  $\mu$ l (5 mg) of the gold suspension, 5  $\mu$ g plasmid construct DNA, 50  $\mu$ l 2.5M  $\text{CaCl}_2$  and 20  $\mu$ l 0.1M spermidine were vortexed, centrifuged  
10 and resuspended in ethanol. The ethanol wash was repeated for a total of 3 times. The final pellet was resuspended in 30  $\mu$ l ethanol, and 5  $\mu$ l of the DNA solution was used per shot. Bombardment may be carried out utilizing any  
15 commercially available gene gun, such as those manufactured and sold by Bio-Rad Laboratories, Hercules, CA. In the present examples, a prototype gene gun provided by Sanford Scientific, Inc., Waterloo, NY was employed at 1100 psi.

#### Selection After Bombardment

20 Three to five days after bombardment, the node segments were transferred to plates containing MS medium without hormones or osmoticum (MSO medium) but containing either 1 mg/L Herbiace™ to select for shoots exhibiting transient expression of the *pat* (*bar*) gene or 0.1 mM  
25 glyphosate to select for transient expression of the *CP4* gene. The MSO medium, without hormones, was used to prevent the formation of callus because it had been previously shown that shoots were not easily regenerated from callus cells of the St. Augustinegrass node segments.

30 Regenerating shoots from the selection plates were transferred to phytatray II (Sigma) for rooting once every month and transplanted to soil when the leaves were about 5-10 cm in length. About 2-3 weeks after transplanting to soil, when the plantlets are growing  
35 nicely, the plantlets are transferred to the greenhouse and treated with the respective herbicides, Herbiace™ or Roundup™, to select for stably transformed plantlets.

-20-

Herbicide rates are established by painting (with a paintbrush) untransformed control plants with different concentrations of the respective herbicide. Herbiace™ at 1.2 mg/ml was found to be lethal for control plants.

5 Therefore, 1.6 mg/ml Herbiace™ was used to ensure that surviving plantlets were transgenic plants stably transformed with the pat gene. Herbicide rates for Roundup™ are established in a similar manner. The recommended concentration (1X) of Roundup™ for lethality for control

10 plants is indicated on the Roundup™ label. To ensure that surviving plantlets are transgenic plants stably transformed with the CP4 gene, both control and presumptively transformed plantlets are treated with Roundup™ at three to five times (3X to 5X), preferably three

15 times, the label-recommended lethal concentration.

The results of the transformations are illustrated in Table 1 and Table 2. Of 930 node segments bombarded with plasmid pSAN41, 26 plantlets were presumptively transformed for resistance to the herbicide,

20 phosphinothricin and, of these, 2 plantlets were stably transformed with the pat gene for the herbicide resistance. Of 660 node segments bombarded with either plasmid pMON25488 or pMON25496, 28 plantlets were presumptively transformed for resistance to the herbicide, glyphosate.

25 Each of these plantlets is then transferred to the greenhouse and treated with the herbicide Roundup™, as described above, to select for plantlets stably transgenic for the CP4 gene.

30 While the invention has been described herein with reference to the preferred embodiments, it is to be understood that it is not intended to limit the invention to the specific forms disclosed. On the contrary, it is intended to cover all modifications and alternative forms

35 falling within the spirit and scope of the invention.

-24-

We claim:

1. A process for producing a transgenic monocotyledonous plant, comprising the steps of:  
providing a node segment from a stem of a  
5 monocotyledonous plant;  
inserting a foreign genetic material into the node segment to alter a physical, biochemical or physiological property of the node segment; and  
subjecting the node segment to culture conditions that  
10 select for regeneration of plantlets expressing the property, without inducing callus formation, to permit direct regeneration of the node segment into a new transgenic plantlet that expresses the property.
2. The process of claim 1, wherein the genetic  
15 material is inserted by microprojectile bombardment.
3. The process of claim 1, wherein the genetic material is inserted by *Agrobacterium*-mediated genetic transfer.
4. The process of claim 1, wherein the genetic  
20 material is inserted by direct DNA uptake mediated by electroporation.
5. The process of claim 1, wherein the node segment is provided from a plant that can be vegetatively propagated.
- 25 6. The process of claim 1, wherein the genetic material is inserted into the node segment within about 48 hours after providing the node segment from the plant.
7. The process of claim 1, wherein the conditions to permit regeneration include culturing the node segment in a  
30 culture medium that does not include a shooting hormone.
8. A process for producing a transgenic monocotyledonous plant, comprising the steps of:  
providing a node segment from a stem of a  
monocotyledonous plant;  
35 inserting a foreign genetic material into a regenerable cell of the node segment followed by the stable integration of the genetic material into the genome of the cell, to produce a genetically transformed cell having an

-25-

altered physical, biochemical or physiological property;  
and

subjecting the node segment to culture conditions that select for regeneration of plantlets expressing the property, without inducing callus formation, to permit direct regeneration of the transformed node segment cell into a new plantlet that expresses the property.

9. A transformed cell from the node segment of claim 8.

10. A transgenic monocotyledonous plant produced by a process of inserting a foreign genetic material into a node segment obtained from a stem of a monocotyledonous plant to alter a physical, biochemical or physiological property of the node segment, and thereafter subjecting the node segment to culture conditions that select for regeneration of plantlets expressing the property, without inducing callus formation, to permit direct regeneration of the node segment into a new transgenic plantlet that expresses the property.

11. The transgenic plant of claim 10, wherein the plant is selected from the group of monocotyledonous plants consisting of a cereal plant, a forage grass, a turfgrass, a herbaceous plant, a woody plant, a vegetable plant and a flowering plant.

12. The transgenic plant of claim 10, wherein the plant is from a family or subfamily selected from *Bambusoideae*, *Arundinoideae*, *Pooideae*, *Phalaenopsis*, *Poaceae*, *Festucoideae*, *Chlorideae*, *Hordeae*, *Zoysieae*, *Agrostideae*, *Festuceae* and *Panicoideae*.

13. The transgenic plant of claim 11, wherein the plant is a turfgrass.

14. The transgenic plant of claim 13, wherein the plant is selected from the group consisting essentially of St. Augustinegrasses, bluegrasses, bentgrasses, bermudagrasses, buffalograsses, redtop, bahiagrasses, centipedegrass, zoysiagrasses, ryegrasses and fescues.

-26-

15. The transgenic plant of claim 10, wherein the genetic material is inserted by microprojectile bombardment.

5 16. The transgenic plant of claim 10, wherein the genetic material is inserted by *Agrobacterium*-mediated genetic transfer.

17. The transgenic plant of claim 10, wherein the genetic material is inserted by direct DNA uptake mediated by electroporation.

10 18. The transgenic plant of claim 10, wherein the plant can be vegetatively propagated.

19. The transgenic plant of claim 10, wherein the property is selected from the group consisting essentially of herbicide resistance, disease resistance, insect  
15 resistance, drought resistance, dwarfism, improved nutrient utilization, antibiotic resistance, expression of a pigment, expression of a fragrance, improved nutritional content, increased production of seed, increased production of fruit, increased stress tolerance, expression of a  
20 regulatory gene to control indigenous genes, reduction of allergenic pollen production, and combinations thereof.

20. A node segment from the transgenic plant of claim 10.

25 21. An embryo cell from the transgenic plant of claim 10.

22. A callus cell from the transgenic plant of claim 10.

23. A protoplast from the transgenic plant of claim 10.

30 24. A fruit from the transgenic plant of claim 10.

25. A vegetable from the transgenic plant of claim 10.

26. A seed from the transgenic plant of claim 10.

27. A leaf from the transgenic plant of claim 10.

28. A meristem from the transgenic plant of claim 10.

35 29. A transgenic St. Augustinegrass plant directly regenerated from a genetically transformed node segment of a St. Augustinegrass plant under culture conditions that do not induce the formation of callus, wherein the transgenic

-27-

plant expresses an altered physical, biochemical or physiological property compared to a St. Augustinegrass plant that is not transgenic for the property.

5           30. The transgenic St. Augustinegrass plant of claim 29, wherein the property is selected from the group consisting essentially of herbicide resistance, disease resistance, insect resistance, drought resistance, dwarfism, improved nutrient utilization, antibiotic resistance, expression of a pigment, expression of a  
10           fragrance, improved nutritional content, increased production of seed, increased production of fruit, increased stress tolerance, expression of a regulatory gene to control indigenous genes, reduction of allergenic pollen production, and combinations thereof.

15           31. A node segment from the transgenic plant of claim 29.

          32. An embryo cell from the transgenic plant of claim 29.

20           33. A callus cell from the transgenic plant of claim 29.

          34. A protoplast from the transgenic plant of claim 29.

          35. A seed from the transgenic plant of claim 29.

          36. A leaf from the transgenic plant of claim 29.

25           37. A meristem from the transgenic plant of claim 29.

          38. A transgenic plant directly regenerated from a genetically transformed node segment of a monocotyledonous plant under culture conditions that do not induce the formation of callus, wherein the transgenic plant expresses  
30           an altered physical, biochemical or physiological property compared to a plant of the same species that is not transgenic for the property.

          39. The transgenic plant of claim 38, wherein the plant is selected from the group of monocotyledonous plants  
35           consisting of a cereal plant, a forage grass, a turfgrass, a herbaceous plant, a woody plant, a vegetable plant and a flowering plant.

-28-

40. The transgenic plant of claim 39, wherein the plant is from a family or subfamily selected from *Bambusoideae*, *Arundinoideae*, *Pooideae*, *Phalaenopsis*, *Poaceae*, *Festucoideae*, *Chlorideae*, *Hordeae*, *Zoysieae*,  
5 *Agrostideae*, *Festuceae* and *Panicoideae*.

41. The transgenic plant of claim 39, wherein the plant is a turfgrass.

42. The transgenic plant of claim 41, wherein the plant is selected from the group consisting essentially of  
10 *St. Augustinegrasses*, *bluegrasses*, *bentgrasses*, *bermudagrasses*, *buffalograsses*, *redtop*, *bahiagrasses*, *centipedegrass*, *zoysiagrasses*, *ryegrasses* and *fescues*.

43. The transgenic plant of claim 38, wherein the property is selected from the group consisting essentially  
15 of herbicide resistance, disease resistance, insect resistance, drought resistance, dwarfism, improved nutrient utilization, antibiotic resistance, expression of a pigment, expression of a fragrance, improved nutritional content, increased production of seed, increased production  
20 of fruit, increased stress tolerance, expression of a regulatory gene to control indigenous genes, reduction of allergenic pollen production, and combinations thereof.

44. A node segment from the transgenic plant of claim 38.

25 45. An embryo cell from the transgenic plant of claim 38.

46. A callus cell from the transgenic plant of claim 38.

30 47. A protoplast from the transgenic plant of claim 38.

48. A fruit from the transgenic plant of claim 38.

49. A vegetable from the transgenic plant of claim 38.

50. A seed from the transgenic plant of claim 38.

51. A leaf from the transgenic plant of claim 38.

35 52. A meristem from the transgenic plant of claim 38.
